January 18, 2016

Abstract

Differential expression analysis between two samples, is a common task in the analysis of RNA-Seq data. In order to identify differential expressed genes, it is crucial that the two compared data sets are normalized. For the task of normalizing gene expression data there are multiple methods available. However all of these methods are based on certain assumptions, these can or can not be suitable for the data which should be normalized. One important question is, how the normalization affects the data and which normalization method and its assumptions apply to the expression data. The *NVT* package provides a fast and simple way to analyze multiple normalization methods via visualization and correlation values. This vignette explains the use of the package and demonstrates a typical work flow.

NVT version: 0.9

If you use *NVT* in published research, please cite:

1 Installation

The latest NVT package can be downloaded from: <https://github.com/Edert/NVT/releases>. The installation of the package can be done directly in R.

```
install.packages(file.path("/home/user/Downloads/", "NVT_1.0.tar.gz"),  
repos=NULL, type="source")
```

2 Standard work flow

Initially the library has to be loaded, which provides access to the data examples 2.1.1 and the *NVT* functions.

```
library("NVT")
```

2.1 Load data

For the demonstration of the *NVT* functions we need gene expression data, so we load the example data provided with the package. We use the two human expression data sets *GSM1275862* and *GSM1275863* from the *airway*[1] package.

2.1.1 Load expression data

We simply load the provided data sets *myexp1* from *GSM1275862*, *myexp2* from *GSM1275863* and the length data per gene as *mylen*.

```
data(mylen)  
data(myexp1)  
data(myexp2)  
  
#show just the first four elements of the loaded data  
head(mylen,4)  
  
##                Length  
## ENSG000000000003    3688  
## ENSG000000000005    1881  
## ENSG000000000419    4032  
## ENSG000000000457   10784  
  
head(myexp1,4)  
  
##                GSM1275862  
## ENSG000000000003         679  
## ENSG000000000005          0  
## ENSG000000000419        467  
## ENSG000000000457        260
```

In order to evaluate the expression between the two RNA-seq expression samples, we have to define a list of human housekeeping genes *GAPDH*, *ALB*, *ACTB*, *QARS*, *PGK2*, *HPRT1*, *ADA* and *POLR2L*.

```
mylist1<-c("ENSG00000111640","ENSG00000163631","ENSG00000075624",
           "ENSG00000172053","ENSG00000170950","ENSG00000165704",
           "ENSG00000196839","ENSG00000177700")
```

2.1.2 Load gene length data

Instead of using the length data generated directly in R or using a simple flat file, it is also possible to load the gene or exon length data directly from an annotation file in gtf or gff format. This function utilizes the [GenomicRanges\[2\]](#) package.

- gff-version: version of the provided gff file [*gff1*, *gff2*, *gff3*, *gtf*]
- gff-feature: feature to use [*default* : *exon*]
- gff-name: name to use [*default* : *gene_id*]

```
#this line gets the path to the gff file provided in the NVT package
#(annotation from Chlamydia trachomatis, ACCESSION: NC_000117 )
mygffpath <- system.file("extdata", "Ctr-D-UW3CX.gff", package = "NVT")
```

```
#this function loads the gff file from the gffpath
mylen1 <- NVTloadgff(mygffpath,"gff3","gene","locus_tag")
```

```
head(mylen1)

##      Length
## CT001    273
## CT002    303
## CT003   1476
## CT004   1467
## CT005   1092
## CT006    570
```

2.2 Generate NVTdata objects

In the first step you need to generate an *NVTdata* object with the *NVTinit* function. Here you have to provide the list of housekeeping genes, the two gene expression samples and the normalization method. Optionally you can also add the gene or exon length data.

The normalization methods are:

- N = No normalization
- TC = Total count normalization
- Med = Median normalization
- TMM = Trimmed Mean of M-values normalization,
- UQ = Upper Quartile normalization
- UQ2 = Upper Quartile normalization (from [NOISeq\[3\]](#))
- Q = Quantile normalization

- RPKM = Reads Per Kilobase per Million mapped reads normalization
- RPM = Reads Per Million mapped reads normalization
- TPM = Transcripts Per Million normalization
- DEQ = Relative log expression method included in the [DESeq\[4\]](#) package
- G = Use the provided genes to normalize

For the most methods no length information is required.

```
mynvt <- NVTinit(mylist1,myexp1,myexp2,"TMM")
```

But for RPKM, RPM and TPM normalization the length data has to be provided.

```
mynvt <- NVTinit(mylist1,myexp1,myexp2,"RPKM",mylen)
```

2.2.1 Normalize the NVTdata

The now initialized *NVTdata* object can be normalized in the next step.

```
mynorm <- NVTnormalize(mynvt)
## [1] "RPKM normalization!"
```

If required the now normalized data can be retrieved easily.

```
mynvalues <- show(mynorm)

head(mynvalues)

##           GSM1275862 GSM1275863
## ENSG000000000003  8.9209656  5.8859979
## ENSG000000000005  0.0000000  0.0000000
## ENSG000000000419  5.6121512  6.1889890
## ENSG000000000457  1.1682249  0.9480595
## ENSG000000000460  0.2395964  0.2196300
## ENSG000000000938  0.0000000  0.0000000
```

2.3 Visualize expression data

One of the key features of *NVT* is the plotting of the XY-Scatter-Plots. This can be done with two functions: *NVTplot* and *NVTadvancedplot*.

2.3.1 Simple plot

The normalized *NVTdata* object can be visualized with the plot function. With the second parameter you can modify the size-ratio of the text and the data points. All expression values are shown as grey dots and the linear model as red line, it is calculated with the data from the housekeeping genes only. The dashed grey line highlights the diagonal, so the perfect correlation between the two data sets.

```
NVTplot(mynorm,0.6)
```

Figure 1: **XY-Scatter-Plot.** The resulting plot from the simple NVTplot function

2.3.2 Advanced plot

The *NVTadvancedplot* plots via [ggplot2](#)[5] and the size parameters control data points, text and labels separately. Here we use the default values of 1 for the data points and the text and increase the labels of the housekeeping genes to 2. Again the grey dots represent the expression data and their density is visualized by the rug in dark red for x- and y-axis. The linear model of the housekeeping gene data is shown in red and the diagonal is highlighted as grey dashed line. As we want to compare different methods we now normalize with the TMM method.

```
mynvt <- NVTinit(mylist1,myexp1,myexp2,"TMM",mylen)
mynorm <- NVTnormalize(mynvt)

## [1] "Trimmed Mean of M-values normalization!"

NVTadvancedplot(mynorm,1,1,2)
```

Scatter plot of: GSM1275862 vs GSM1275863

Trimmed Mean of M-values (TMM) normalized

Figure 2: **Advanced XY-Scatter-Plot.** The *NVTadvancedplot* function results in a plot produced by *ggplot2* with a rug on both axis, indicating the density of the data-points

2.4 Correlation values

In addition to the graphical representation of the gene expression data, the correlation coefficients of the housekeeping genes of the two samples can be calculated with the functions *NVTpearson*, *NVTrmsd* and *NVTmae*.

2.4.1 Pearson correlation

The Pearson correlation coefficient of the normalized expression of the housekeeping genes is calculated with the following command, using an already normalized *NVTdata* object.

```
NVTpearson(mynorm)

##      pearson      p-value
## 0.9636246988 0.0001170673
```

2.4.2 RMSD and MEA correlation

The root mean square error (RMSE) also called the root mean square deviation (RMSD) is calculated with the *NVTrmsd* function.

```
NVTrmsd(mynorm)

##      RMSD
## 9097.041
```

And the mean absolute error (MAE) can be calculated and retrieved with the *NVTmae* function.

```
NVTmae(mynorm)

##      MAE
## 3855.185
```

2.5 Test all methods

To test more normalization methods on the provided data sets in one single step, the correlation coefficients of all implemented normalization methods can be calculated with the *NVTtestall* function. It requires a normalized *NVTdata* object and the correlation coefficient you are interested in. The method can be defined with:

- p = Pearson correlation
- rmsd = root mean square deviation
- mae = mean absolute error

```
NVTtestall(mynorm, "p")

## [1] "No normalization!"
## [1] "Total count normalization!"
## [1] "Median normalization!"
## [1] "Trimmed Mean of M-values normalization!"
```

```
## [1] "Upper Quartile normalization!"
## [1] "Upper Quartile normalization (from NOISeq)!"
## [1] "Quantile normalization!"
## [1] "RPKM normalization!"
## [1] "RPM normalization!"
## [1] "DESeq normalization!"
## [1] "Using DESeq"
## [1] "Input counts are not integer, converting them!"
## [1] "TPM normalization!"
## [1] "Normalization by given gene-set!"
